## **Description**

The package **MuMIn** contains functions to streamline information-theoretic model selection and carry out model averaging based on the information criteria.

#### Details

The collection of functions includes:

dredge performs automated model selection with subsets of the supplied 'global' model, and optional choices of other model properties (such as different link functions). The set of models may be generated either with 'all possible' combinations, or tailored according to the conditions specified.

pdredge does the same, but can parallelize model fitting process using a cluster.

model.sel creates a model selection table from hand-picked models.

model.avg calculates model averaged parameters, with standard errors and confidence intervals.

AICc calculates second-order Akaike information criterion.

For a complete list of functions, use library(help = "MuMIn").

By default,  $AIC_c$  is used to rank the models and to obtain model selection probabilities, though any other information criteria can be utilised. At least the following ones are currently implemented in R: AIC and BIC in package **stats**, and QAIC, QAICC, ICOMP, CAICF, and Mallows' Cp in **MuMIn**. There is also DIC extractor for MCMC models, and QIC for GEE.

Most of R's common modelling functions are supported, for a full inventory see list of supported models.

AICc 3

#### See Also

AIC, step or stepAIC for stepwise model selection by AIC.

## **Examples**

AICc

Second-order Akaike Information Criterion

## Description

Calculate second-order Akaike information criterion for one or several fitted model objects (AIC $_c$ , AIC for small samples).

## Usage

```
AICc(object, ..., k = 2, REML = NULL)
```

## **Arguments**

object a fitted model object for which there exists a logLik method, or a logLik object.

optionally more fitted model objects.

k the 'penalty' per parameter to be used; the default k = 2 is the classical AIC.

REML optional logical value, passed to the logLik method indicating whether the restricted log-likelihood or log-likelihood should be used. The default is to use the

method used for model estimation.

## Value

If just one object is provided, returns a numeric value with the corresponding  $AIC_c$ ; if more than one object are provided, returns a data. frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and  $AIC_c$ .

4 AICc

#### Note

 $AIC_c$  should be used instead AIC when sample size is small in comparison to the number of estimated parameters (Burnham & Anderson 2002 recommend its use when n/K < 40).

Beetle 5

Beetle

Flour beetle mortality data

## **Description**

Mortality of flour beetles ( $Tribolium\ confusu$ ) due to exposure to gaseous carbon disulfide  $CS_2$ , from Bliss (1935).

## Usage

```
data(Beetle)
```

#### **Format**

Beetle is a data frame with 5 elements.

dose The dose of CS<sub>2</sub> in mg/L

n.tested Number of beetles tested

n.killed Number of beetles killed

Prop A matrix with two columns named n.killed and n.survived

mortality Observed mortality rate.

Cement

Cement hardening data

## **Description**

Cement hardening data from Woods et al (1939).

## Usage

data(Cement)

#### **Format**

Cement is a data frame with 5 variables. x1-x4 are four predictor variables expressed as a percentage of weight.

- X1 calcium aluminate
- X2 tricalcium silicate
- X3 tetracalcium alumino ferrite
- X4 dicalcium silicate
- y calories of heat evolved per gram of cement after 180 days of hardening.

|--|

# Description

Generate a set of models with combinations (subsets) of the terms in the global model, with optional rules for model inclusion.

# Usage

```
dredge(global.model, beta = FALSE, evaluate = TRUE, rank = "AICc",
    fixed = NULL, m.max = NA, m.min = 0, subset, marg.ex = NULL,
    trace = FALSE, varying, extra, ct.args = NULL, ...)

## S3 method for class 'model.selection'
print(x, abbrev.names = TRUE, warnings = getOption("warn") != -1L, ...)
```

# Arguments

global.model	a fitted 'global' model object. See 'Details' for a list of supported types.
beta	logical, should standardized coefficients be returned?
evaluate	whether to evaluate and rank the models. If FALSE, a list of model calls is returned.
rank	optional custom rank function (information criterion) to be used instead AICc, e.g. AIC, QAIC or BIC. See 'Details'.
fixed	optional, either a single sided formula or a character vector giving names of terms to be included in all models. See 'Subsetting'.
m.max, m.min	optionally, the maximum and minimum number of terms in a single model (excluding the intercept), m.max defaults to the number of terms in global.model. See 'Subsetting'.
subset	logical expression describing models to keep in the resulting set. See 'Subsetting'.
marg.ex	a character vector specifying names of variables for which NOT to check for marginality restrictions when generating model formulas. If this argument is set to TRUE, all combinations of terms are used (i.e. no checking). If NA or missing, the exceptions will be found based on the terms of global.model. See 'Details'.
trace	if TRUE, all calls to the fitting function (i.e. updated global.model calls) are printed before actual fitting takes place.
varying	optionally, a named list describing the additional arguments to vary between the generated models. Item names correspond to the arguments, and each item provides a list of choices (i.e. list(arg1 = list(choice1, choice2,),)). Complex elements in the choice list (such as family objects) should be either named (uniquely) or quoted (unevaluated, e.g. using alist, see quote), otherwise it may produce rather unpleasant effects. See example in Beetle.
extra	optional additional statistics to include in the result, provided as functions, function names or a list of such (best if named or quoted). Similarly as in rank argument, each function must accept fitted model object as an argument and

return a (value coercible to a) numeric vector. These can be e.g. additional information criterions or goodness-of-fit statistics. The character strings "R^2" and "adjR^2" are treated in a special way, and will add a likelihood-ratio based  $R^2$  and modified- $R^2$  respectively to the result (this is more efficient than using r.squaredLR directly).

x a model. selection object, returned by dredge.

abbrev.names should printed variable names be abbreviated? (useful with many variables).

warnings if TRUE, errors and warnings issued during the model fitting are printed below the table (currently, only with pdredge). To permanently remove the warnings,

set the object's attribute "warnings" to NULL.

ct.args optional list of arguments to be passed to coefTable (e.g. dispersion param-

eter for glm affecting standard errors used in subsequent model averaging).

optional arguments for the rank function. Any can be an expression (of mode call), in which case any x within it will be substituted with a current model.

#### **Details**

Models are fitted one by one through repeated evaluation of modified calls to the global.model (in a similar fashion as with update). This approach, while robust in that it can be applied to a variety of different model object types is not very efficient and may be time-intensive.

Note that the number of combinations grows exponentially with number of predictor variables  $(2^N, less)$  when interactions are present, see below). As there can be potentially a large number of models to evaluate, to avoid memory overflow the fitted model objects are not stored in the result. To get (a subset of) the models, use get.models on the object returned by dredge.

For a list of model types that can be used as a global.model see list of supported models. Modelling functions not storing call in their result should be evaluated *via* the wrapper created by updateable.

**Information criterion:** rank is found by a call to match. fun and may be specified as a function or a symbol (e.g. a back-quoted name) or a character string specifying a function to be searched for from the environment of the call to dredge. The function rank must accept model object as its first argument and always return a scalar. Typical choice for rank would be "AIC", "BIC", or "QAIC".

**Interactions:** dredge by default respects marginality constraints, so "all possible combinations" do not include models containing interactions without their respective main effects and all lower order terms. This behaviour can be altered by marg.ex argument, which can be used to allow for simple nested designs. For example, with global model of form a / (x + z), one would use marg.ex = "a" and fixed = "a". If global.model uses such a formula and marg.ex is missing or NA, it will be adjusted automatically.

**Subsetting:** There are three ways to constrain the resulting set of models: setting limits to the number of terms in a model with m.max and m.min, binding term(s) to all models with fixed, and more complex rules can be applied using argument subset. To be included in the selection table, the model formulation must satisfy all these conditions.

subset can take either a form of an *expression* or a *matrix*. The latter should be a lower triangular matrix with logical values, where columns and rows correspond to global.model terms. Value subset["a", "b"] == FALSE will exclude any model containing both terms a and b. Values other than FALSE (or 0) are taken as TRUE.

In the form of expression, the argument subset acts in a similar fashion to that in the function subset for data. frames: model terms can be referred to by name as variables in the expression, with the difference being that they are always logical (i.e. TRUE if a term exists in the model).

There is also . (x) and . (+x) notation that indicate respectively any or all model terms including a *variable* x. This concerns only interactions containing a particular main effect x (e.g. x:z, v:x:z), and *not* a variable in a complex expression, such as x in log(x) or  $I(x^2)$ . This is only useful with marginality exceptions, see marg. ex argument.

The expression can contain any of the global.model terms (getAllTerms(global.model) lists them), as well as names of the varying argument items. Names of global.model terms take precedence when identical to names of varying, so to avoid ambiguity varying variables in subset expression should be enclosed in V() (e.g. subset = V(family) = "Gamma" assuming that varying is something like list(family = c(..., "Gamma"))).

If element names in varying are missing, the elements themselves are used. Call and symbol elements are represented as character values (via deparse), and everything except numeric, logical, character and NULL values is replaced by item numbers (e.g. varying = list(family = list(..., Gamma) should be referred to as subset = V(family) == 2. This can quickly become confusing, therefore it is recommended to use named lists in most cases. demo(dredge.varying) provides examples.

The subset expression can also contain variable '\*nvar\*' (needs to be backtick-quoted), which is equal to number of terms in the model (**not** the number of estimated parameters K).

To make inclusion of a variable conditional on presence of some other variable, a function dc ("dependency chain") can be used in the subset expression. dc takes any number of variables as arguments, and allows a variable to be included only if all preceding variables are also present (e.g. subset = dc(a, b, c) allows for models of form a, a+b and a+b+c but not b, c, b+c or a+c).

subset expression can have a form of an unevaluated call, expression object, or a one sided formula. See 'Examples'. Compound model terms (such as 'as-is' expressions within I() or smooths in gam) should be treated as non-syntactic names and enclosed in back-ticks (e.g. subset = 's(x, k = 2)' || 'I(log(x))', see Quotes). Mind the spacing, names must match exactly the term names as given by getAllTerms. To simply keep certain terms in all models, use of argument fixed is more efficient. Note that the fixed formula is interpreted in the same manner as model formula and so the terms need not to be quoted.

subset *expression syntax summary:* 

```
a & b indicates that model terms a and b must be present (see 'Logical Operators')
V(x) indicates a varying variable x
.(x) indicates that at least one term containing variable x must be present
.(+x) indicates that all the terms containing variable x must be present
dc(a, b, c,...) 'dependency chain': a is allowed only if b is present, and b only if c is present, etc.
'*nvar*' number of variables
```

**Missing values:** Use of na.action = "na.omit" (R's default) or "na.exclude" in global.model must be avoided, as it results with sub-models fitted to different data sets, if there are missing values. Error is thrown if it is detected.

**Methods:** There are subset and plot methods, the latter produces a graphical representation of model weights and variable relative importance. Coefficients can be extracted with coef or coefTable.

## Value

dredge returns an object of class model.selection, being a data.frame with models' coefficients (or presence/NA for factors), df - number of parameters, log-likelihood, the information criterion

value, delta-IC and *Akaike weight*. Models are ordered by the value of the information criterion specified by rank (lowest on top).

The attribute "calls" is a list containing the model calls used (arranged in the same order as the models). A model call can be retrieved with getCall(\*, i) where i is a vector of model index or name (if given as character string).

Other attributes: "global" - the global.model object, "rank" - the rank function used, "call" - the matched call, and "warnings" - list of errors and warnings given by the modelling function during the fitting, with model number appended to each.

#### Note

Users should keep in mind the hazards that a "thoughtless approach" of evaluating all possible models poses. Although this procedure is in certain cases useful and justified, it may result in selecting a spurious "best" model, due to the model selection bias.

"Let the computer find out" is a poor strategy and usually reflects the fact that the researcher did not bother to think clearly about the problem of interest and its scientific setting (Burnham and Anderson, 2002).

#### Author(s)

Kamil Bartoń

#### See Also

pdredge is a parallelized version of this function (uses a cluster).

get.models, model.avg. model.sel for manual model selection tables.

Possible alternatives: glmulti in package glmulti and bestglm (bestglm). regsubsets in package leaps also performs all-subsets regression.

Lasso variable selection provided by various packages, e.g. glmnet, lars or glmmLasso.

```
# Example from Burnham and Anderson (2002), page 100:
data(Cement)
options(na.action = "na.fail")  # prevent fitting models to different datasets

fm1 <- lm(y ~ ., data = Cement)
dd <- dredge(fm1)
subset(dd, delta < 4)

# Visualize the model selection table:
if(require(graphics))
    plot(dd)

# Model average models with delta AICc < 4
model.avg(dd, subset = delta < 4)

#or as a 95% confidence set:
model.avg(dd, subset = cumsum(weight) <= .95) # get averaged coefficients

#'Best' model
summary(get.models(dd, 1))[[1]]</pre>
```

12 Formula manipulation

```
## Not run:
# Examples of using 'subset':
# keep only models containing X3
dredge(fm1, subset = ~ X3) # subset as a formula
dredge(fm1, subset = expression(X3)) # subset as expression object
# the same, but more effective:
dredge(fm1, fixed = "X3")
# exclude models containing both X1 and X2 at the same time
dredge(fm1, subset = !(X1 && X2))
# Fit only models containing either X3 or X4 (but not both);
# include X3 only if X2 is present, and X2 only if X1 is present.
dredge(fm1, subset = dc(X1, X2, X3) \&\& xor(X3, X4))
# the same as above, but without using "dc"
dredge(fm1, subset = (X1 | !X2) && (X2 | !X3) && xor(X3, X4))
# Include only models with up to 2 terms (and intercept)
dredge(fm1, m.max = 2)
## End(Not run)
# Add R^2 and F-statistics, use the 'extra' argument
dredge(fm1, m.max = 1, extra = c("R^2", F = function(x))
    summary(x)$fstatistic[[1]]))
# with summary statistics:
dredge(fm1, m.max = 1, extra = list(
    "R^2", "*" = function(x) {
        s <- summary(x)</pre>
        c(Rsq = s$r.squared, adjRsq = s$adj.r.squared,
            F = s$fstatistic[[1]])
    })
)
# Add other information criterions (but rank with AICc):
dredge(fm1, m.max = 1, extra = alist(AIC, BIC, ICOMP, Cp))
```

Formula manipulation Manipulate model formulas

## **Description**

simplify. formula rewrites a formula using shorthand notation. Currently only the factor crossing operator \* is applied, so that expanded expression such as a+b+a:b becomes a\*b. expand. formula does the opposite, additionally expanding other expressions, i.e. all nesting (/), grouping and ^.

## Usage

```
simplify.formula(x)
expand.formula(x)
```

get.models 13

#### **Arguments**

Χ

a formula or an object from which it can be extracted (such as a fitted model object).

## Author(s)

Kamil Bartoń

## See Also

```
formula
```

delete.response, drop.terms, and reformulate

# **Examples**

```
simplify.formula(y \sim a + b + a:b + (c + b)^2)
simplify.formula(y \sim a + b + a:b + 0)
expand.formula(\sim a \times b)
```

get.models

Get models

## Description

Generate a list of fitted model objects from a model.selection table. pget.models can use paralell computation in a cluster to do that.

## Usage

```
get.models(object, subset, ...)
pget.models(object, cluster = NA, subset, ...)
```

## **Arguments**

object object returned by dredge.

subset subset of models, an expression evaluated within the model selection table, see the subset method. If it is a character vector, it is interpreted as names of rows to be selected. By default, all model objects are fitted and returned (see 'Note').

... additional arguments to update the models. For example, in 1me one may want to use method = "REML" while using "ML" for model selection.

cluster a cluster object. See pdredge for details.

## Value

list of fitted model objects.

14 importance

## Note

As of version 1.6.3, the default behaviour (if subset argument is missing) is to return all the models, rather than a 'confidence set' with delta <= 4.

## Author(s)

Kamil Bartoń

#### See Also

```
dredge, model.avg
```

## **Examples**

importance

Relative variable importance

# Description

Sum of 'Akaike weights' over all models including the explanatory variable.

## Usage

```
importance(x)
```

## **Arguments**

Χ

Either a list of fitted model objects, or a "model.selection" or "averaging" object.

## Value

a numeric vector of relative importance values, named as the predictor variables.

## Author(s)

Kamil Bartoń

## See Also

```
Weights
dredge, model.avg, mod.sel
```

Information criteria 15

#### **Examples**

```
# Generate some models
data(Cement)
fm1 <- lm(y \sim ., data = Cement)
ms1 <- dredge(fm1)
# Importance can be calculated/extracted from various objects:
importance(ms1)
## Not run:
importance(subset(mod.sel(ms1), delta <= 4))</pre>
importance(model.avg(ms1, subset = delta <= 4))</pre>
importance(subset(ms1, delta <= 4))</pre>
importance(get.models(ms1, delta <= 4))</pre>
## End(Not run)
# Re-evaluate the importances according to BIC
# note that re-ranking involves fitting the models again
# 'nobs' is not used here for backwards compatibility
lognobs <- log(length(resid(fm1)))
importance(subset(mod.sel(ms1, rank = AIC, rank.args = list(k = lognobs)),
    cumsum(weight) <= .95))
# This gives a different result than previous command, because 'subset' is
# applied to the original selection table that is ranked with 'AICc'
importance(model.avg(ms1, rank = AIC, rank.args = list(k = lognobs),
    subset = cumsum(weight) <= .95))</pre>
```

Information criteria Various information criteria

## **Description**

Calculate Mallows' Cp and Bozdogan's ICOMP and CAIFC information criteria.

Extract or calculate Deviance Information Criterion from MCMCg1mm and mer object.

# Usage

```
Cp(object, ..., dispersion = NULL)
ICOMP(object, ..., REML = NULL)
CAICF(object, ..., REML = NULL)
DIC(object, ...)
```

# Arguments

```
object a fitted model object (in case of ICOMP and CAICF, logLik and vcov methods must exist for the object). For DIC, an object of class MCMCglmm or mer.

... optionally more fitted model objects.
```

dispersion the dispersion parameter. If NULL, it is inferred from object.

REML

optional logical value, passed to the logLik method indicating whether the restricted log-likelihood or log-likelihood should be used. The default is to use the method used for model estimation.

#### **Details**

Mallows' Cp statistic is the residual deviance plus twice the estimate of  $\sigma^2$  times the residual degrees of freedom. It is closely related to AIC (and a multiple of it if the dispersion is known).

ICOMP (I for informational and COMP for complexity) penalizes the covariance complexity of the model, rather than the number of parameters directly.

CAICF (C is for 'consistent' and F denotes the use of the Fisher information matrix) includes with penalty the natural logarithm of the determinant of the estimated Fisher information matrix.

#### Value

If just one object is provided, the functions return a numeric value with the corresponding IC; otherwise a data. frame with rows corresponding to the objects is returned.

```
merge.model.selection Combine model selection tables
```

## **Description**

Combine two or more model selection tables.

## Usage

```
## S3 method for class 'model.selection'
merge(x, y, suffixes = c(".x", ".y"), ...)
## S3 method for class 'model.selection'
rbind(..., deparse.level = 1)
```

merge.model.selection 17

## **Arguments**

```
    x, y model.selection objects to be combined.
    suffixes a character vector with two elements that are appended respectively to row names of the combined tables
    ... model.selection objects for rbind, ignored in merge
    deparse.level currently ignored.
```

## Value

A model. selection object containing the selected models (rows).

#### Note

both delta IC values and IC-weights are recalculated in the resulting tables.

Models in the combined model selection tables must be comparable, i.e. fitted to the same data, however only very basic checking is done to verify that. The models must also be ranked by the same information criterion.

Unlike the merge method for data. frame, this method simply appends second table to the first.

18 Model utilities

Model utilities

Model utility functions

## **Description**

These functions extract or calculate various values from provided fitted model objects(s). They are mainly meant for internal use, but may be also useful for end-users.

beta.weights computes standardized coefficients (beta weights) for a model;

coeffs extracts model coefficients;

getAllTerms extracts independent variable names from a model object;

coefTable extracts a table of coefficients, standard errors and associated degrees of freedom when possible;

model.names generates shorthand (alpha)numeric names for one or several fitted models;

## Usage

```
beta.weights(model)

coeffs(model)

getAllTerms(x, ...)
## S3 method for class 'terms'
getAllTerms(x, offset = TRUE, intercept = FALSE, ...)

coefTable(model, ...)
## S3 method for class 'lme'
coefTable(model, adjustSigma, ...)
## S3 method for class 'gee'
coefTable(model, ..., type = c("naive", "robust"))

model.names(object, ..., labels = NULL, use.letters = FALSE)
```

# Arguments

model	a fitted model object.
object	a fitted model object or a list of such objects.
X	a fitted model object or a formula.
offset	should 'offset' terms be included?
intercept	should terms names include the intercept?
labels	optionally, a character vector with names of all the terms, e.g. from a global model. model.names enumerates the model terms in order of their appearance in the list and in the models. So, changing the order of the models would lead to different names. The argument 'labels' can be used to prevent this happening.
•••	for model.names, more fitted model objects. For coefTable arguments that are passed to appropriate vcov or summary method (e.g. dispersion parameter for

glm may be used here). In other functions often not used.

model.avg

use.letters logical, whether letters should be used instead of numeric codes.

type for GEE models, the type of covariance estimator to calculate returned standard

errors on. Either "naive" or "robust" ('sandwich').

adjustSigma See summary.lme.

## **Details**

The functions coeffs, getAllTerms and coefTable provide interface between the model object and model.avg (and dredge). Custom methods can be written to provide support for additional classes of models.

## Note

coeffs's value is in most cases identical to that returned by coef, the only difference being it returns fixed effects' coefficients for mixed models, and the value is always a named numeric vector.

Use of tTable is deprecated in favour of coefTable.

## Author(s)

Kamil Bartoń

model.avg

Model averaging

## **Description**

Model averaging based on an information criterion.

## Usage

```
model.avg(object, ..., revised.var = TRUE)

## Default S3 method:
model.avg(object, ..., beta = FALSE, rank = NULL, rank.args = NULL,
    revised.var = TRUE, dispersion = NULL, ct.args = NULL)

## S3 method for class 'model.selection'
model.avg(object, subset, fit = FALSE, ..., revised.var = TRUE)
```

## **Arguments**

object	a fitted model object or a list of such objects, or a model.selection object. Structure 'Details'.	
	for default method, more fitted model objects. Otherwise, arguments that are passed to the default method.	
beta	logical, should standardized coefficients be returned?	

20 model.avg

rank optionally, a custom rank function (information criterion) to use instead of AICc, e.g. BIC or QAIC, may be omitted if object is a model list returned by get.models or a model. selection object. See 'Details'. optional list of arguments for the rank function. If one is an expression, an x rank.args within it is substituted with a current model. revised.var logical, indicating whether to use revised formula for standard errors. See par. avg. the dispersion parameter for the family used. See summary.glm. This is used dispersion currently only with glm, is silently ignored otherwise. optional list of arguments to be passed to coefTable (besides dispersion). ct.args see subset method for model. selection object. subset fit if TRUE, the component models are fitted using get.models. See 'Details'.

#### Details

model.avg may be used either with a list of models, or directly with a model.selection object (e.g. returned by dredge). In the latter case, the models from the model selection table are not evaluated unless the argument fit is set to TRUE or some additional arguments are present (such as rank or dispersion). This results in much faster calculation, but has certain drawbacks, because the fitted component model objects are not stored, and some methods (e.g. predict, fitted, model.matrix or vcov) would not be available with the returned object. Otherwise, get.models is called prior to averaging, and ... are passed to it.

For a list of model types that are accepted see list of supported models.

rank is found by a call to match. fun and typically is specified as a function or a symbol (e.g. a back-quoted name) or a character string specifying a function to be searched for from the environment of the call to lapply. rank must be a function able to accept model as a first argument and must always return a scalar.

Several standard methods for fitted model objects exist for class averaging, including summary, predict, coef, confint, formula, and vcov.

coef, vcov, confint and coefTable accept argument full that if set to TRUE, the full model-averaged coefficients are returned, rather than subset-averaged ones (when full = FALSE, being the default).

logLik returns a list of logLik objects for the component models.

#### Value

An object of class averaging is a list with components:

summary a data.frame with log-likelihood, IC, Delta(IC) and Akaike weights for the

component models.

coef.shrinkage a vector of full model-averaged coefficients, see 'Note'.

coefArray an array of component models' coefficients, their standard errors, and degrees

of freedom.

term. codes names of the terms with numerical codes used in the summary.

avg.model the model averaged parameters. A data.frame containing averaged coeffi-

cients, unconditional standard error, adjusted SE (if dfs are available) and z-values (coefficient and SE) and significance (assuming a normal error distribu-

tion).

model.avg 21

importance relative importance of the predictor variables (including interactions), calculated

as a sum of the Akaike weights over all of the models in which the parameter of

interest appears.

term. names character vector giving names of all terms in the model.

x, formula the model matrix and formula corresponding to the one that would be used in a

single model. formula contains only the averaged coefficients.

call the matched call.

In addition, the object has following attributes:

modelList a list of component model objects.

beta logical, were standardized coefficients used?

revised.var if TRUE, the standard errors were calculated with the revised formula (See par.avg).

#### Note

The 'subset' (or 'conditional') average only averages over the models where the parameter appears. An alternative, the 'full' average assumes that a variable is included in every model, but in some models the corresponding coefficient (and its respective variance) is set to zero. Unlike the 'subset average', it does not have a tendency of biasing the value away from zero. The 'full' average is a type of shrinkage estimator and for variables with a weak relationship to the response they are smaller than 'subset' estimators.

Averaging models with different contrasts for the same factor would yield nonsense results, currently no checking for contrast consistency is done.

From version 1.0.1, print method provides only a concise output (similarly as for lm). To print a full summary of the results use summary function. Confidence intervals can be obtained with confint.

AICc has examples of averaging models fitted by REML.

modavg in package **AICcmodavg**, and coef.glmulti in package **glmulti** also perform model averaging.

22 model.sel

#### **Examples**

```
# Example from Burnham and Anderson (2002), page 100:
data(Cement)
fm1 <- lm(y \sim ., data = Cement)
(ms1 <- dredge(fm1))</pre>
#models with delta.aicc < 4</pre>
summary(model.avg(ms1, subset = delta < 4))</pre>
#or as a 95% confidence set:
avgmod.95p <- model.avg(ms1, cumsum(weight) <= .95)</pre>
confint(avgmod.95p)
## Not run:
# The same result, but re-fitting the models via 'get.models'
confset.95p <- get.models(ms1, cumsum(weight) <= .95)</pre>
model.avg(confset.95p)
\mbox{\tt\#} Force re-fitting the component models
model.avg(ms1, cumsum(weight) <= .95, fit = TRUE)</pre>
# Models are also fitted if additional arguments are given
model.avg(ms1, cumsum(weight) <= .95, rank = "AIC")</pre>
## End(Not run)
## Not run:
# using BIC (Schwarz's Bayesian criterion) to rank the models
BIC <- function(x) AIC(x, k = log(length(residuals(x))))
model.avg(confset.95p, rank = BIC)
\mbox{\tt\#} the same result, using AIC directly, with argument k
# 'x' in a quoted 'rank' argument is substituted with a model object
# (in this case it does not make much sense as the number of observations is
# common to all models)
model.avg(confset.95p, rank = AIC, rank.args = alist(k = log(length(residuals(x)))))
## End(Not run)
```

model.sel

model selection table

## **Description**

Build a model selection table.

## Usage

```
model.sel(object, ...)
## S3 method for class 'model.selection'
model.sel(object, rank = NULL, rank.args = NULL, ..., beta = FALSE, extra)
```

model.sel 23

```
## Default S3 method:
model.sel(object, ..., rank = NULL, rank.args = NULL, beta = FALSE, extra)
```

## **Arguments**

object A fitted model object, a list of such objects, or a "model.selection" object.

... More fitted model objects.

rank Optional, custom rank function (information criterion) to use instead of AICc, e.g. QAIC or BIC, may be omitted if object is a model list returned by get.models.

rank.args Optional list of arguments for the rank function. If one is an expression, an x within it is substituted with a current model.

beta logical, should standardized coefficients be returned?

optional additional statistics to include in the result, provided as functions, func-

tion names or a list of such (best if named or quoted). See dredge for details.

#### Value

extra

An object of class "model.selection" with columns containing useful information about each model: the coefficients, df, log-likelihood, the value of the information criterion used, Delta(IC) and 'Akaike weight'. If any arguments differ between the modelling function calls, the result will include additional columns showing them (except for formulas and some other arguments).

# or
# model.sel(msAICc, rank = AIC, rank.args = alist(k = log(nobs(x))))
# or
# update(msAICc, rank = AIC, rank.args = alist(k = log(nobs(x))))</pre>
```

24 MuMIn-models

MuMIn-models

List of supported models

## **Description**

List of model classes accepted by model.avg, model.sel, and dredge.

#### **Details**

Fitted model objects that can be used with model selection and model averaging functions include those returned by:

```
• 1m, glm (package stats);
```

- rlm, glm.nb and polr (MASS);
- multinom (nnet);
- lme, gls (nlme);
- lmer, glmer (lme4);
- gam, gamm\* (mgcv);
- gamm4\* (gamm4);
- glmmML (glmmML);
- glmmadmb (glmmADMB from R-Forge);
- asreml (asreml, non-free commercial package; REML comparisons only);
- hurdle, zeroinfl (pscl);
- negbin, betabin (class glimML, package aod);
- aodml, aodql (aods3);
- betareg (betareg);
- sarlm, spautolm (spdep);
- spml\* (if fitted by ML, splm);
- coxph, survreg (survival);
- coxme, lmekin (coxme);
- rq (quantreg);
- clm and clmm (ordinal);
- logistf (logistf);
- crunch\*, pgls (caper);
- functions from package **unmarked** (within the class unmarkedFit);
- mark and related functions (class mark from package RMark). Note currently dredge can
  only manipulate formula element of the argument model.parameters, keeping its other elements intact.

Generalized Estimation Equation model implementations: geeglm from package geepack, gee from gee, and yags from yags (from R-Forge) can be used with QIC as the selection criterion.

 $MCMCglmm^*$  models (package MCMCglmm) with e.g. DIC as the rank function are accepted by model.sel and dredge.

Other classes are also likely to be supported, in particular if they inherit from one of the above classes. In general, the models averaged with model.avg may belong to different types (e.g. glm and gam), provided they use the same data and response, and if it is valid to do so. This applies also to constructing model selection tables with model.sel.

par.avg 25

## Note

\* In order to use gamm, gamm4, spml (> 1.0.0), crunch or MCMCglmm with dredge, an updateable wrapper for these functions should be created.

```
model.avg, model.sel and dredge.
```

par.avg Parameter averaging

## **Description**

Average a single model coefficient based on provided weights. It is mostly intended for internal use.

## Usage

```
par.avg(x, se, weight, df = NULL, level = 1 - alpha, alpha = 0.05,
    revised.var = TRUE, adjusted = TRUE)
```

## Arguments

x vector of parameters.
se vector of standard errors.

weight vector of weights.

df (optional) vector of degrees of freedom.

alpha, level significance level for calculating confidence intervals.

revised.var logical, should the revised formula for standard errors be used? See 'Details'.

adjusted logical, should the inflated standard errors be calculated? See 'Details'.

#### **Details**

Unconditional standard errors are square root of the variance estimator, calculated either according to the original equation in Burnham and Anderson (2002, equation 4.7), or a newer, revised formula from Burnham and Anderson (2004, equation 4) (if revised.var = TRUE, this is the default). If adjusted = TRUE (the default) and degrees of freedom are given, the adjusted standard error estimator and confidence intervals with improved coverage are returned (see Burnham and Anderson 2002, section 4.3.3).

## Value

par. avg returns a vector with named elements:

Coefficient model coefficients,

SE unconditional standard error,

Adjusted SE adjusted standard error,

Lower CI, Upper CI

unconditional confidence intervals.

model.avg for model averaging.

pdredge

Automated model selection using parallel computation

## Description

Parallelized version of dredge.

## Usage

```
pdredge(global.model, cluster = NA, beta = FALSE, evaluate = TRUE, rank = "AICC",
    fixed = NULL, m.max = NA, m.min = 0, subset, marg.ex = NULL, trace = FALSE,
   varying, extra, ct.args = NULL, check = FALSE, ...)
```

## **Arguments**

```
global.model, beta, evaluate, rank
                 see dredge.
fixed, m.max, m.min, subset, marg.ex, varying, extra, ct.args, ...
                 see dredge.
trace
                  displays the generated calls, but may not work as expected since the models are
                 evaluated in batches rather than one by one.
                 either a valid cluster object, or NA for a single threaded execution.
cluster
```

check either integer or logical value controlling how much checking for existence and

correctness of dependencies is done on the cluster nodes. See 'Details'.

#### **Details**

All the dependencies for fitting the global. model, including the data and any objects the modelling function will use must be exported into the cluster worker nodes (e.g. via clusterExport). The required packages must be also loaded thereinto (e.g. via clusterEvalQ(..., library(package)), before the cluster is used by pdredge.

If check is TRUE or positive, pdredge tries to check whether all the variables and functions used in the call to global.model are present in the cluster nodes' .GlobalEnv before proceeding further. This causes false errors if some arguments of the model call (other than subset) would be evaluated in data environment. In that case using check = FALSE (the default) is desirable.

If check is TRUE or greater than one, pdredge will compare the global.model updated at the cluster nodes with the one given as argument.

#### Value

See dredge.

predict.averaging

Predict method for the averaged model

## **Description**

Model-averaged predictions with optional standard errors.

# Usage

```
## S3 method for class 'averaging'
predict(object, newdata = NULL, se.fit = FALSE,
    interval = NULL, type = NA, backtransform = FALSE, full = TRUE, ...)
```

# Arguments

object	An object returned by model.avg.
newdata	An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
se.fit	logical, indicates if standard errors should be returned. This has any effect only if the predict methods for each of the component models support it.

predict.averaging 29

interval Currently not used.

type The type of predictions to return (see documentation for predict appropriate

for the class of used component models). If omitted, the default type is used.

See 'Details'.

backtransform If TRUE, the averaged predictions are back-transformed from link scale to re-

sponse scale. This makes sense provided that all component models use the same family, and the prediction from each of the component models is calculated on the link scale (as specified by type. For glm, use type = "link"). See

'Details'.

full If TRUE, the full model averaged coefficients are used (only if se.fit = FALSE

and the component objects are a result of 1m).

... Arguments to be passed to respective predict method (e.g. level for lme

model).

#### **Details**

predicting is possible only with averaging objects with "modelList" attribute, i.e. those created *via* model.avg from a model list, or from model.selection object with argument fit = TRUE (note this will recreate the model objects which may be time consuming, see model.avg).

If all the component models are oridinary linear models, the prediction can be made either with the full averaged coefficients (the argument full = TRUE this is the default) or subset-averaged coefficients. Otherwise the prediction is obtained by calling predict on each component model and weighted averaging the results, which corresponds to the assumption that all predictors are present in all models, but those not estimated are equal zero. See 'Note' in model.avg. Predictions from component models with standard errors are passed to par.avg and averaged in the same way as the coefficients.

Predictions on the response scale from generalized models can be calculated by averaging predictions of each model on the link scale, followed by inverse transformation (this is achieved with type = "link" and backtransform = TRUE). This is only possible if all component models use the same family and link function. Alternatively, predictions from each model on response scale may be averaged (with type = "response" and backtransform = FALSE). Note that this leads to results differing from those calculated with the former method. See also predict.glm.

#### Value

If se.fit = FALSE, a vector of predictions, otherwise a list with components: fit containing the predictions, and se.fit with the estimated standard errors.

## Note

This method relies on availability of the predict methods for the component model classes (except when all component models are of class 1m).

The package **MuMIn** includes predict methods for lme, gls and lmer (**Ime4**), all of which can calculate standard errors of the predictions (with se.fit = TRUE). The former two enhance the original predict methods from package **nlme**, and with se.fit = FALSE they return identical result. **MuMIn**'s versions are always used in averaged model predictions (so it is possible to predict with standard errors), but from within global environment they will be found only if **MuMIn** is before **nlme** on the search list (or directly extracted from namespace as MuMIn:::predict.lme).

predict method for mer models currently can only calculate values on the outermost level (equivalent to level = 0 in predict.lme).

QAIC

Quasi AIC or AICc

## **Description**

Calculate a modification of Akaike's Information Criterion for overdispersed count data (or its version corrected for small sample, "quasi-AIC<sub>c</sub>"), for one or several fitted model objects.

# Usage

```
QAIC(object, ..., chat, k = 2)
QAICc(object, ..., chat, k = 2)
```

## **Arguments**

```
object a fitted model object. ... optionally, more fitted model objects. chat \hat{c}, the variance inflation factor. k the 'penalty' per parameter.
```

## Value

If only one object is provided, returns a numeric value with the corresponding QAIC or  $QAIC_c$ ; otherwise returns a data. frame with rows corresponding to the objects.

#### Note

 $\hat{c}$  is the dispersion parameter estimated from the global model, and can be calculated by dividing model's deviance by the number of residual degrees of freedom.

In calculation of QAIC, the number of model parameters is increased by 1 to account for estimating the overdispersion parameter. Without overdispersion,  $\hat{c} = 1$  and QAIC is equal to AIC.

Note that glm does not compute maximum-likelihood estimates in models within the *quasi*-family. In case it is justified, and with a proper caution, a workaround could be used by 'borrowing' the aic element from the corresponding 'non-quasi' family (see 'Example').

## End(Not run)
```

QIC

QIC and quasi-Likelihood for GEE

## **Description**

Calculate quasi-likelihood under the independence model criterion (QIC) for Generalized Estimating Equations.

#### Usage

```
QIC(object, ..., typeR = FALSE)
QICu(object, ..., typeR = FALSE)
quasiLik(object, ...)
```

# Arguments

object a fitted model object of class gee, geepack or yags. . . . for QIC and  $QIC_u$ , optionally more fitted model objects.

typeR logical, whether to calculate QIC(R). QIC(R) is based on quasi-likelihood of a working correlation R model. Defaults to FALSE, and QIC(I) based on indepen-

dence model is returned.

#### Value

If just one object is provided, returns a numeric value with the corresponding QIC; if more than one object are provided, returns a data. frame with rows corresponding to the objects and one column representing QIC or  $QIC_u$ .

r.squaredGLMM 33

## Note

This implementation is based partly on (revised) code from packages **yags** (R-Forge) and **ape**. The functions are still in experimental stage and should be used with caution.

Methods exist for gee (package **gee**), geeglm (**geepack**), and yags (**yags** on R-Forge). yags and compar. gee from package **ape** both provide QIC values.

## **Examples**

 ${\tt r.squaredGLMM}$ 

Pseudo-R-squared for Generalized Mixed-Effect models

## **Description**

Calculate a conditional and marginal coefficient of determination for Generalized mixed-effect models ( $R^2_{GLMM}$ ).

## Usage

```
r.squaredGLMM(x, nullfx = NULL)
```

34 r.squaredGLMM

## **Arguments**

x a fitted linear model object.

nullfx optionally, a fitted *null* model including only intercept and all the random effects of the reference model.

#### **Details**

For mixed-effects models,  $R^2$  can be categorized into two types: marginal and conditional. **Marginal**  $\mathbf{R}^2$  represents the variance explained by fixed factors, and is defined as:

$$R^2_{GLMM(m)} = \frac{\sigma_f^2}{\sigma_f^2 + \sum_{l=1}^u \sigma_l^2 + \sigma_\epsilon^2}$$

**Conditional \mathbb{R}^2** is interpreted as variance explained by both fixed and random factors (i.e. the entire model), and is calculated according to the equation:

$$R^2_{GLMM(c)} = \frac{\sigma_f^2 + \sum_{l=1}^u \sigma_l^2}{\sigma_f^2 + \sum_{l=1}^u \sigma_l^2 + \sigma_\epsilon^2}$$

where  $\sigma_f^2$  is the variance of the fixed effect components, and  $\sum \sigma_l^2$  is the sum of all u variance components (group, individual, etc.), and  $\sigma_\epsilon^2$  is the residual variance.

#### Value

r. squaredGLMM returns a numeric vector with two values for marginal and conditional  $R^2_{GLMM}$ .

## Note

 $R_{GLMM}^2$  can be calculated also for fixed-effect models. In the simpliest case of OLS it reduces to var(fitted) / (var(fitted) + deviance / 2). Yet, unlike likelihood-ratio based  $R^2$  for OLS, value of this statistic differs from that of the classical  $R^2$ .

Currently methods exist for classes: mer(Mod), lme, glmmML and (g)lm.

See note in r. squaredLR help page for comment on using R<sup>2</sup> in model selection.

This implementation is based on R code from 'Supporting Information' for Nakagawa & Schielzeth (2012).

This function is in experimental stage and should be used with caution. Specifically, conditional  $R_{GLMM}^2$  for Poisson family models cannot be yet calculated (NA is returned).

r.squaredLR(fm1, null.RE = TRUE)
}</pre>
```

r.squaredLR

Likelihood-ratio based pseudo-R-squared

## **Description**

Calculate a coefficient of determination based on the likelihood-ratio test  $(R_{LR}^2)$ .

# Usage

```
r.squaredLR(x, null = NULL, null.RE = FALSE)
null.fit(x, evaluate = FALSE, RE.keep = FALSE, envir = NULL)
```

## **Arguments**

X	a fitted model object.
null	a fitted <i>null</i> model. If not provided, null.fit will be used to construct it. null.fit's capabilities are limited to only a few model classes, for others the <i>null</i> model has to be specified manually.
null.RE	logical, should the null model contain random factors? Only used if no <i>null</i> model is given, otherwise omitted, with a warning.
evaluate	if TRUE evaluate the fitted model object else return the call.
RE.keep	if TRUE, the random effects of the original model are included.
envir	the environment in which the $null$ model is to be evaluated, defaults to the environment of the original model's formula.

## **Details**

This statistic is is one of the several proposed pseudo-R-squared's for nonlinear regression models. It is based on an improvement from *null* (intercept only) model to the fitted model, and calculated as

$$R_{LR}^2 = 1 - \exp(-\frac{2}{n}(\log Lik(x) - \log Lik(0)))$$

where  $\log Lik(x)$  and  $\log Lik(0)$  are the log-likelihoods of the fitted and the null model respectively. ML estimates are used for this purpose in when models have been fitted by REstricted ML (by calling logLik with argument REML = FALSE). Note that the null model can include the random factors of the original model, in which case the statistic represents the 'variance explained' by fixed effects.

36 subset.model.selection

For OLS models the value is consistent with classical  $R^2$ . In some cases (e.g. in logistic regression), the maximum  $R_{LR}^2$  is less than one. The modification proposed by Nagelkerke (1991) adjusts the  $R_{LR}^2$  to achieve 1 at its maximum:  $\bar{R}^2 = R_{LR}^2/\max(R_{LR}^2)$  where  $\max(R_{LR}^2) = 1 - \exp(\frac{2}{n}\log Lik(0))$ .

null.fit tries to guess the *null* model call, given the provided fitted model object. This would be usually a glm. The function will give an error for an unrecognized class.

#### Value

r.squaredLR returns a value of  $R_{LR}^2$ , and the attribute "adj.r.squared" gives the Nagelkerke's modified statistic. Note that this is not the same as nor equivalent to the classical 'adjusted R squared'.

null. fit returns the fitted null model object (if evaluate = TRUE) or an unevaluated call to fit a null model.

## Note

 $R^2$  is a useful goodness-of-fit measure as it has the interpretation of the proportion of the variance 'explained', but it performs poorly in model selection, and is not suitable for use in the same way as the information criterions.

subset.model.selection
```

Subsetting model selection table

## **Description**

Return subsets of a model selection table returned by dredge or model.sel.

## Usage

```
## S3 method for class 'model.selection'
subset(x, subset, select, recalc.weights = TRUE,
recalc.delta = FALSE, ...)
## S3 method for class 'model.selection'
x[i, j, recalc.weights = TRUE, recalc.delta = FALSE, ...]
```

subset.model.selection 37

## **Arguments**

X	a model. selection object to be subsetted.
subset,select	logical expressions indicating columns and rows to keep. See subset.
i,j	indices specifying elements to extract.
recalc.weights	logical value specyfying whether Akaike weights should be normalized across the new set of models to sum to one.
recalc.delta	logical value specyfying whether $delta[IC]$ should be calculated for the new set of models (this is not done by default).
	further arguments passed to [.data.frame.

#### Value

A model.selection object containing only the selected models (rows). When columns are selected (arguments select or j are provided), a plain data. frame is returned.

## Note

Unlike the method for data.frame, extracting with only one index (i.e. x[i]) will select rows rather than columns.

To select rows according to presence or absence of the variables (rather than their value), a pseudo-function has may be used, e.g. subset(x, has(a, !b)) will select rows with a and without b (this is equivalent to !is.na(a) & is.na(b)). has can take any number of arguments. Importantly, the has() notation cannot be used in the subset argument for dredge, where the variable names should be given directly, with the same effect.

To select rows where one variable can be present conditional on the presence of other variable(s), the function dc ( $\mathbf{d}$ ependency  $\mathbf{c}$ hain) can be used. dc takes any number of variables as arguments, and allows a variable to be included only if all the preceding arguments are also included (e.g. subset = dc(a, b, c) allows for models of form a, a+b and a+b+c but not b, c, b+c or a+c).

dredge, subset and [.data.frame for subsetting and extracting from data.frames.

```
data(Cement)
fm1 <- lm(formula = y ~ X1 + X2 + X3 + X4, data = Cement)

# generate models where each variable is included only if the previous
# are included too, e.g. X2 only if X1 is there, and X3 only if X2 and X1
dredge(fm1, subset = dc(X1, X2, X3, X4))

# which is equivalent to
# dredge(fm1, subset = (!X2 | X1) & (!X3 | X2) & (!X4 | X3))

# alternatively, generate "all possible" combinations
ms0 <- dredge(fm1)
# ...and afterwards select the subset of models</pre>
```

38 updateable

```
subset(ms0, dc(X1, X2, X3, X4))
# which is equivalent to
# subset(ms0, (has(!X2) | has(X1)) & (has(!X3) | has(X2)) & (has(!X4) | has(X3)))
# Different ways of finding a confidence set of models:
# delta(AIC) cutoff
subset(ms0, delta <= 4, recalc.weights = FALSE)
# cumulative sum of Akaike weights
subset(ms0, cumsum(weight) <= .95, recalc.weights = FALSE)
# relative likelihood
subset(ms0, (weight / weight[1]) > (1/8), recalc.weights = FALSE)
```

updateable

Make a function return updateable result

## **Description**

Creates a function wrapper that stores a call in the values returned by its argument FUN.

## Usage

```
updateable(FUN)
updateable2(FUN, Class)

# updateable wrapper for mgcv::gamm and gamm4::gamm4
uGamm(formula, random = NULL, ..., lme4 = inherits(random, "formula"))
```

## **Arguments**

FUN function to be modified, found via match. fun.

Class optional character vector naming class(es) to be set onto the result of FUN (not possible with formal S4 objects).

formula, random, ... arguments to be passed to gamm or gamm4

lme4 if TRUE, gamm4 is called, gamm otherwise.

#### **Details**

Most model fitting functions in R returns an object that can be updated or re-fitted via update. This is thanks to the call stored in the object, which can be used (possibly modified) later on. It is also utilised by dredge to generate sub-models.

Some functions (such as gamm or MCMCglmm) do not provide their result with the call element. In this case updateable can be used on that function to add it. The resulting wrapper should be used in exactly the same way as the original function.

## Value

A function with the same arguments as FUN, wrapping a call to FUN and adding an element named call to its result if possible, or an attribute "call" (if the returned value is atomic or a formal S4 object).

updateable 39

## Note

uGamm sets also an appropriate class onto the result ("gamm4" and/or "gamm"), which is needed for some generics defined in **MuMIn** to work (note that unlike the functions created by updateable it has no formal arguments of the original function). As of version 1.9.2, MuMIn::gamm is no longer available.

**MuMIn** replaces the default method for getCall (defined originally in package **stats**), with a function that can extract the call also when it is an **attribute** (rather than an element of the object).
